CATLISTS TOKEN

A token sale framework for CTL

Project Whitepaper · Draft for review

Token: Catlists Token (CTL) **Network:** Ethereum **Supply:** 3,000,000 CTL

DOCUMENT STATUS
Working draft — requires project-owner review before publication.

Version 0.1 · 22 October 2026
Prepared from the supplied Catlists ICO requirements questionnaire. Commercial, legal, token-economic and technical details remain subject to confirmation.

Important notice

This document is a preliminary project whitepaper draft prepared from the requirements supplied for Catlists. It organizes the current concept and proposed token-sale mechanics. It is not an offer to sell securities or tokens, investment advice, a guarantee of returns, or legal, tax or financial advice.

The source questionnaire states that the project whitepaper is in progress. The project vision, utility, team, roadmap milestones, legal entity details, risk disclosures and final tokenomics were not provided in full. Missing details are marked as pending confirmation rather than presented as established facts.

No investment return, exchange listing, liquidity, future value or commercial outcome is promised. A token sale can involve loss of funds, smart-contract vulnerabilities, market volatility, regulatory restrictions and operational risks. Obtain independent legal and security reviews before a public launch.

Contents

• 1. Project overview

• 2. Project scope and intended platform

• 3. Token overview

• 4. Token sale structure

• 5. Vesting and claims

• 6. Technical architecture

• 7. Roadmap

• 8. Risks and safeguards

• 9. Open items and finalisation checklist

1. Project overview

Catlists is the project name associated with Catlists Token (CTL). The supplied requirements specify an Ethereum-based token with a total supply of 3,000,000 CTL and a planned sale comprising three presale rounds followed by a public sale. The intended contribution assets are ETH and USDT.

At this stage, the source material defines token-sale and platform requirements more clearly than the wider business model. A final publication should add the problem Catlists addresses, target users, product or service being built, and the role CTL is intended to play.

Project facts currently supplied

Item	Current specification
Project / token	Catlists Token (CTL)
Blockchain	Ethereum
Maximum token supply	3,000,000 CTL
Contribution assets	ETH and USDT
Sale stages	Presale 1, Presale 2, Presale 3, Public Sale
Vesting	20% at TGE, remainder monthly over 12 months
Staking	Later phase; excluded from initial sale scope

2. Project scope and intended platform

The requirements describe a web-based ICO crowdfunding experience connected to a user's MetaMask wallet. The platform is expected to present project information, tokenomics, roadmap, FAQs, sale details and a whitepaper. The requested visual direction is monochrome black and white with colourful imagery.

Investor experience

• **Wallet connection:** users connect MetaMask to interact with the sale.

• **Contributions:** investors contribute using ETH or USDT, subject to the active sale round.

• **Purchase records:** token purchase amounts and contribution events are recorded by the smart contract.

• **Vesting information:** the application may show purchased, claimed and vesting-related data.

• **Email notifications:** requested by the client; these require an off-chain service and are not a feature of the token contract itself.

Administration and reporting

The questionnaire requests one administrator with access to user-related records, sale-round configuration, allocation records, fundraising statistics, transaction history, website content and downloadable reports. These functions require an application backend and administrative interface in addition to the smart contracts. Blockchain data should remain the source of truth for on-chain transactions.

Scope boundary

Staking is expressly deferred until after launch. This draft does not define staking rewards, lock-up periods, reward funding, penalties or staking-contract behaviour.

3. Token overview

CTL is planned as an ERC-20 fungible token on Ethereum. The supplied total supply is 3,000,000 tokens. The final deployment should state whether this is a hard-capped supply and how tokens are divided between sale inventory, team, ecosystem, liquidity, treasury, partnerships and other allocations.

Preliminary token summary

Parameter	Value / status
Token name	Catlists Token
Ticker	CTL
Standard	ERC-20
Network	Ethereum intended; testnet deployment requested for development
Total supply	3,000,000 CTL
Decimals	18 assumed for implementation; confirm before deployment
Token utility	Not specified in questionnaire — project owner to define

Token allocation table — pending

No allocation percentages were provided for sale rounds or other purposes. These allocations must be approved and total 100% of the 3,000,000 CTL supply before this whitepaper can be considered final.

4. Token sale structure

The planned sale sequence consists of three presale rounds followed by a public sale. The questionnaire gives prices for the three presale rounds and indicates that each round lasts 30 days. It requests automatic start and stop behaviour based on time and fundraising limits.

Sale stages

Stage	Specified price	Duration	Allocation
Presale Round 1	0.0005*	30 days	Pending
Presale Round 2	0.0010*	30 days	Pending
Presale Round 3	0.0015*	30 days	Pending
Public Sale	Pending	Pending	Pending

* The price denomination was not stated in the questionnaire. USDT per CTL is a working assumption only and must be confirmed by the project owner.

Contribution handling

The intended accepted assets are ETH and USDT. If prices are denominated in USDT, ETH contributions require a reliable oracle price conversion. The final implementation must use verified oracle addresses for the selected network, reject stale or invalid price data, and clearly communicate estimates and transaction costs.

Round completion and transitions

Each round should stop accepting contributions when its end time or token allocation limit is reached. The next round must not begin until its start conditions are satisfied. Smart contracts do not execute themselves: fully automatic progression requires a keeper or a transaction-triggered transition mechanism.

Fundraising target

The questionnaire describes the target as “3M token sales”. This draft interprets that as up to 3,000,000 CTL sold, but the intended allocation and whether the full supply is available for sale must be confirmed.

5. Vesting and claims

The requested schedule releases 20% of purchased tokens at the Token Generation Event (TGE), followed by the remaining 80% monthly over 12 months. The schedule should be implemented transparently and consistently unless the project owner approves different rules for different rounds.

Vesting summary

Milestone	Unlock	Cumulative unlock
At TGE	20%	20%
Monthly tranches	Remaining 80% split across 12 months	Increases monthly
After month 12	Final tranche completes vesting	100%

Claiming

The questionnaire says investors should not claim directly through the website, while also requiring vesting and token-claim functionality in the smart contract. A claim function may therefore be available on-chain without a dedicated website claim button. The final user journey should be agreed before deployment.

Vesting details to confirm

• Whether the first monthly tranche occurs exactly 30 days after TGE or at a calendar-month boundary.

• Whether vesting begins from the TGE timestamp for every round or depends on purchase date.

• How rounding dust is handled for very small purchases.

• Whether unclaimed tokens remain available indefinitely.

• Whether refunds or sale cancellation affect vesting.

6. Technical architecture

The intended product combines on-chain contracts with an off-chain web application. Contracts manage token balances, contribution accounting, sale limits and vesting claims. The website and backend provide presentation, email notifications, administrative tools, reporting and transaction indexing.

On-chain components

• **CTL ERC-20 contract:** defines token metadata and supply.

• **ICO sale contract:** manages round configuration, supported contributions, inventory accounting and purchase events.

• **Vesting / claim logic:** calculates unlocked tokens and transfers claimable CTL.

• **Oracle integration:** uses verified feeds with freshness checks if ETH is accepted against a stable-denominated price.

Off-chain components

• **Frontend:** project pages, wallet connection, sale-round information and investor views.

• **Backend / indexer:** processes blockchain events for searchable history and dashboard summaries.

• **Admin panel:** authorised management of supported configuration and website content.

• **Notifications and exports:** email messages and downloadable reports based on verified event data.

Security principles

Use established contract libraries, minimise privileged operations, validate oracle data, guard external transfers against reentrancy, test boundary conditions and secure administrative keys. A multisignature wallet is recommended for production administration. Contract verification and an independent security audit should be completed before mainnet launch.

7. Roadmap

The supplied questionnaire does not include approved roadmap milestones or dates. The following is a proposed delivery framework for discussion, not a confirmed commitment or launch schedule.

Phase 1 — Specification

Confirm CTL utility, allocations, sale prices and denomination, round dates, TGE, vesting details and legal requirements.

Phase 2 — Contract development

Implement ERC-20, sale-round configuration, ETH/USDT contribution handling, vesting and claim functionality.

Phase 3 — Testnet validation

Run unit, integration and security tests covering oracle conditions, allocation limits, contributions and vesting.

Phase 4 — Platform integration

Connect wallet flows, sale information, transaction indexing, dashboard reporting and admin tools.

Phase 5 — Independent review

Complete code review, independent audit, operational runbooks and launch-readiness checks.

Phase 6 — Launch preparation

Confirm final parameters, verify contracts, secure administrative keys and publish approved documentation.

Later phase — Staking

Design staking separately after launch, including reward source, rate, lock periods and withdrawal rules.

8. Risks and safeguards

Smart-contract risk. Defects, edge cases or privileged-key compromise can cause loss of funds or incorrect token distribution. Independent audit and testing are essential.

Oracle and pricing risk. Incorrect, stale or unavailable feeds may affect ETH conversion. Use network-specific verified feeds and fail safely when data is invalid.

Market risk. Token prices can fluctuate significantly. No future price, liquidity or return is guaranteed.

Regulatory risk. Token sales may be subject to securities, consumer-protection, sanctions, tax, privacy and other rules. Obtain qualified legal advice.

Operational risk. Lost keys, website downtime, compromised email systems or inaccurate indexing can affect users.

Token allocation risk. Unclear sale inventory, vesting reserves or allocation percentages can create supply and trust issues.

Stablecoin risk. USDT depends on its issuer, supported network and token contract. Verify the exact asset address and transfer behaviour.

Minimum launch safeguards

• Independent smart-contract audit and documented remediation of findings.

• Testnet deployment with reproducible test cases and end-to-end simulations.

• Multisig protection for owner privileges and a documented incident-response plan.

• Verified contract addresses and published sale parameters.

• Clear user disclosures covering fees, vesting, risks, eligibility and supported networks.

9. Open items and finalisation checklist

The following items should be answered by the project owner before this document is published or used to solicit contributions.

Open item	Required decision
Token price denomination	Confirm whether prices are USDT per CTL, ETH per CTL or another unit.
Sale allocations	Specify CTL allocation for each stage and reconcile total supply.
Public sale	Set price, duration, start conditions and allocation.
Token utility	Explain exactly what CTL is used for in the Catlists ecosystem.
Project vision	Define problem, target audience, product scope and intended outcomes.
Team and entity	Add verified team biographies, legal entity and contact details, where applicable.
TGE date	Confirm expected TGE timing and whether it can change.
Vesting precision	Confirm 30-day intervals versus calendar months and unclaimed-token treatment.
Sale operation	Confirm whether a keeper is planned for round transitions.
Legal review	Confirm jurisdiction, eligibility restrictions, disclosures and compliance.
Security audit	Set audit scope and launch acceptance criteria.

Closing statement

Catlists' current specification establishes the intended token name, ticker, Ethereum network, planned supply, contribution assets, sale stages and vesting outline. The project owner must complete the outstanding business, tokenomics, legal and operational decisions so the whitepaper accurately reflects the final product. This draft should not be treated as final marketing or investment material until those decisions have been confirmed and reviewed.

Document version: 0.1 · Draft date: 22 October 2026 · Prepared from the client-provided requirements questionnaire.
